A Network Model for Dynamic Identity Federation

Dipl.-Inf. Yang Xiang, Rechenzentrum der Max-
Planck-Gesellschaft in Garching

Most existing approaches to identity federation are based on static relationships. This leads to problems with scalability and deployment in confederations. We introduce an underlying network and trust model for dynamic federation as an attempt to overcome the shortages of static federations. Furthermore, we present an implementation of the dynamic federation and a WebDav client which works together with the dynamic federation.
